

EVALUATING THE EFFECTIVENESS OF UTILISING CUE CARDS FOR BAND 5 NURSES IN ASSISTING RESUS TEAM DURING RAPID SEQUENCE INDUCTION (RSI)

HANNAH FRITZIE J. ORTEGA

BACKGROUND

The Emergency Department (ED) is a fast-paced environment where nurses need to know how to safely assist with rapid sequence induction (RSI) of critically ill patients. Band 5 nurses comprise the majority of nursing staff levels in the department, which led to the author to discover this group's knowledge of rapid sequence induction (RSI). The purpose of the researcher is to find out if cue cards would help Band 5 nurses in performing their role in assisting the Resus team in urgent situations during RSI.

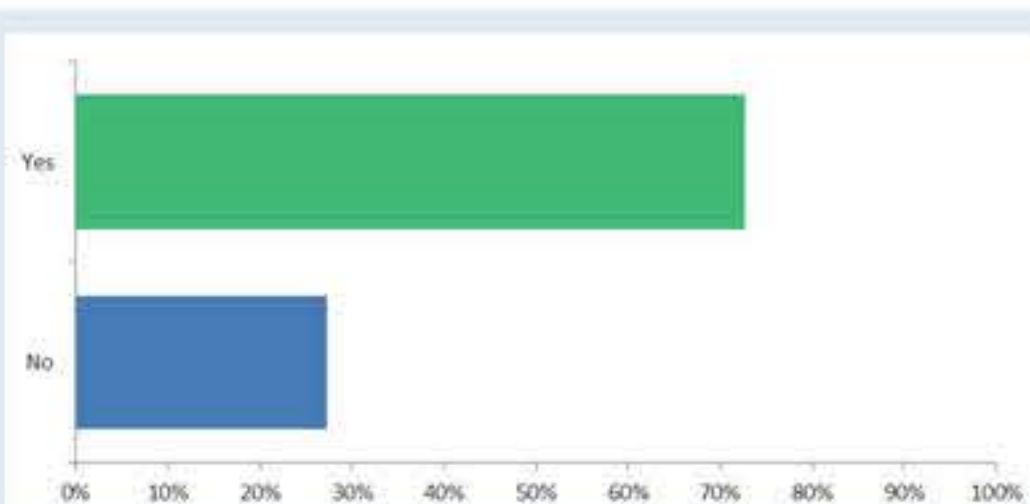

Intervention: RSI cue card distributed

METHODOLOGY

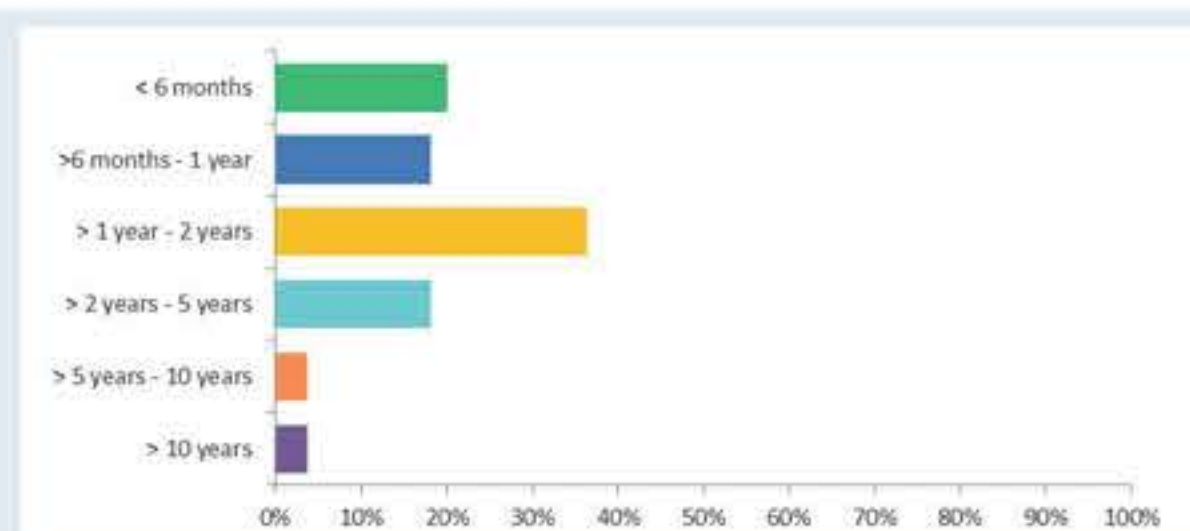

This study is a quantitative research project and the researcher utilised non-**probability purposive homogeneous sampling technique** to select respondents suitable for the study. A survey was distributed and the researcher facilitated the study from July 2024 to Sept 2024.

N ~ 85 Band 5 nurses

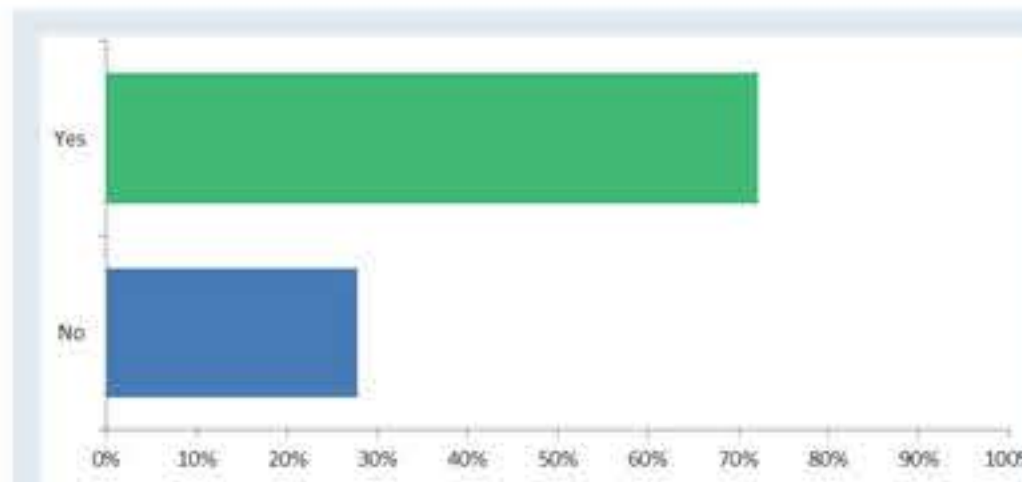

Before cue card was given n ~ 61 (71.76% of the N)
After cue card was given n ~ 55 (64% of the N)

More than 70% of the band 5 nurses have the knowledge and skills to assist with RSI. However, **greater than 27% stated they lacked confidence to assist during RSI's.**

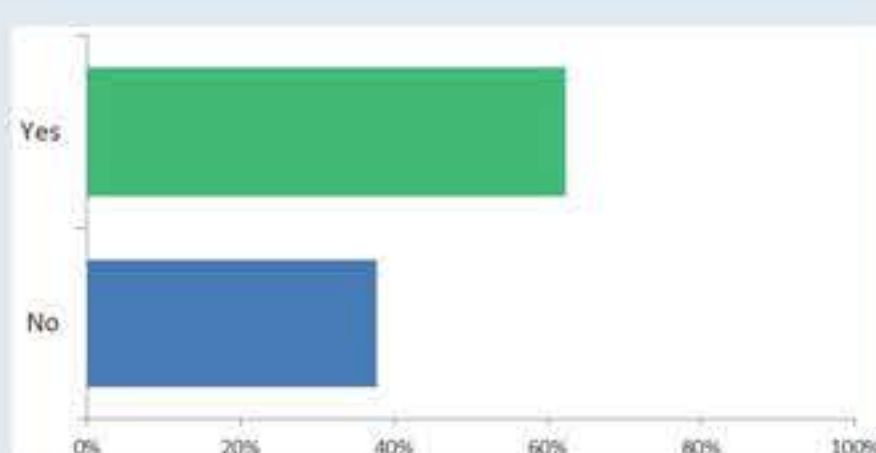

A significant proportion of ED band 5 nurses were in post for more than 1 to 2 years accounting for 36.36%. **The smallest proportion are band 5 nurses with more than 5 to 10 years' and greater than 10 years of experience, the sum total is 6.56%.** Nurses with less than 6 months experience and those with greater than 6 months to 1 year have 16.39% and 14.75% respectively.

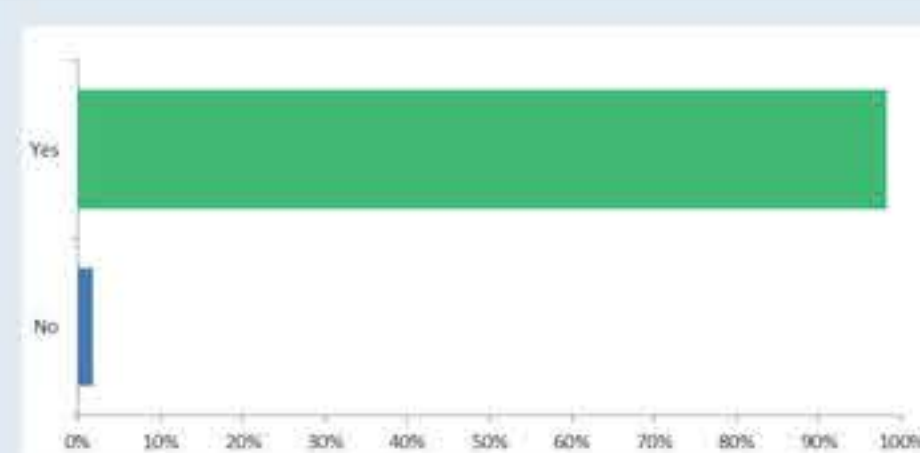

Around 78% participated in RSI but it needs to be noted **that 27% of Band 5 nurses have not been involved in RSI to date.**

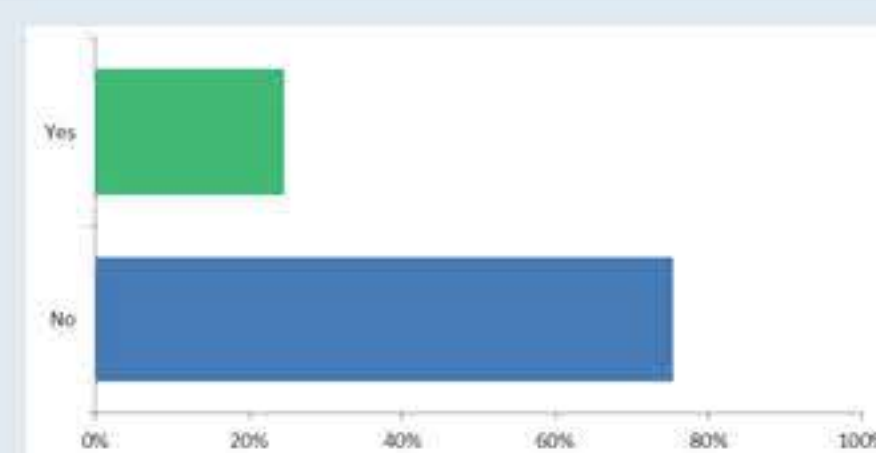

RESULTS

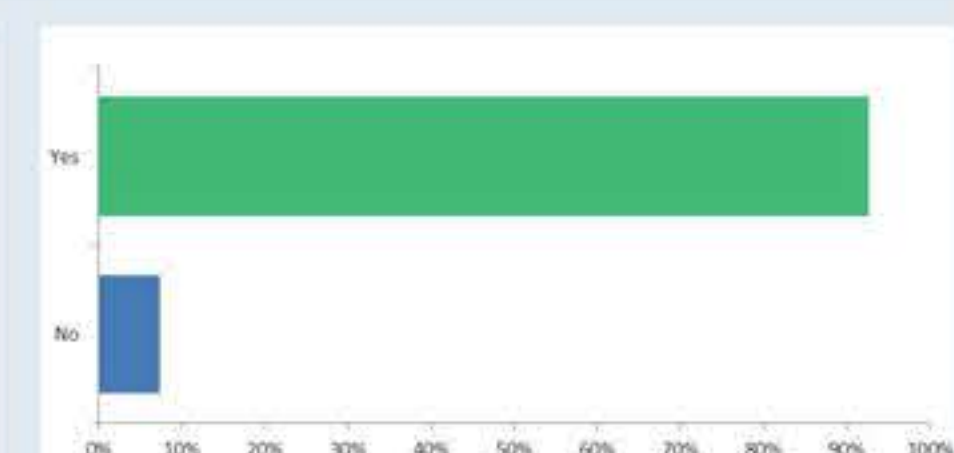

Knowledge of drugs - Before

Knowledge of the drug - After

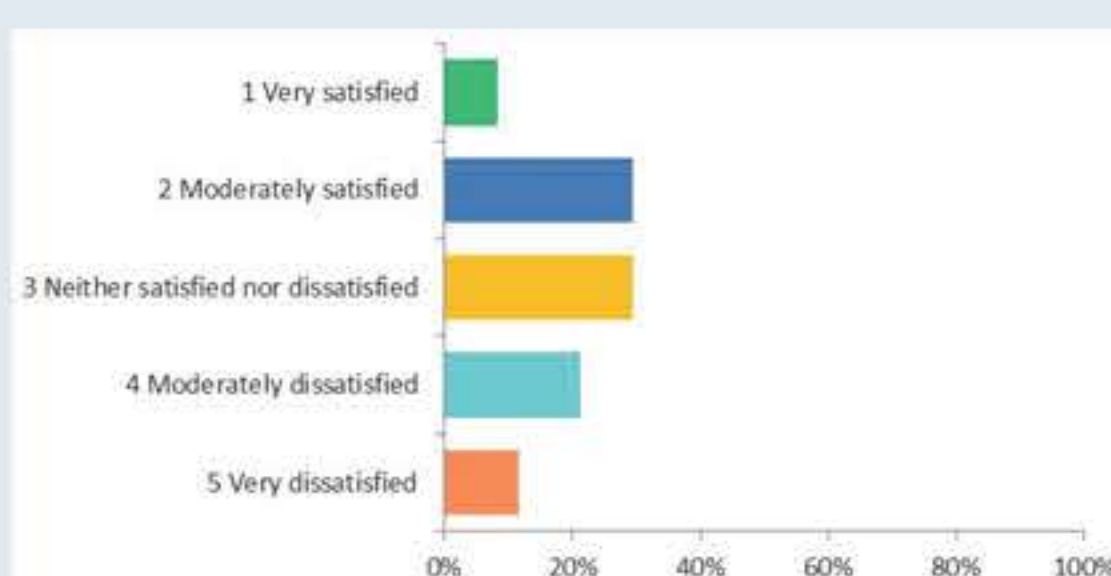

Knowledge of drug doses - Before

Knowledge of drug doses - After

There was a **significant increase in the number of Band 5 nurses' knowledge of drugs from 57% to 98.1%** and **knowledge of the drug dosages increased significantly from 44.6% to 92.59%** after the cue cards were distributed.

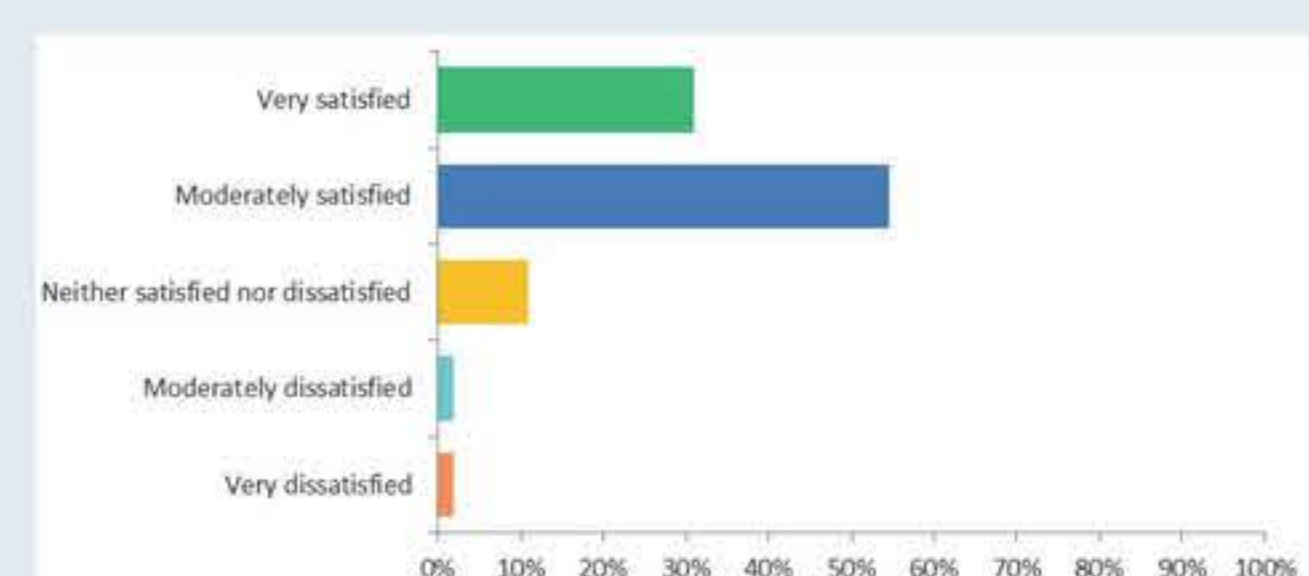

Satisfaction in their level of knowledge - Before

Before the cue cards were given, only **8.20% were very satisfied with their level of knowledge of RSI** and a relatively low percentage was very dissatisfied (11.48%).

There was a significant increase in satisfaction in their level of knowledge among the cohort of Band 5 nurses after receiving the cue cards. **30.91% were very satisfied - three times more than before the cue cards were given at 8.2%.**

In contrast, **only 1.82% were very dissatisfied with their level of knowledge after receiving the cue cards.** Before the cue cards were given, 11.49% felt very dissatisfied with their knowledge, which is a significant decrease of 9.67%.

Satisfaction in their level of knowledge - After

CONCLUSION

The RSI cue cards were very helpful among the Band 5 nurses. They increased the level of their knowledge and confidence in assisting colleagues performing RSI in urgent situations.

The cue cards included information where the medications were stored, indications, dosages, contraindications/cautions, route and education.

RECOMMENDATIONS:

To educators, the author's recommendation is to use and hand out RSI cue card to increase Band 5 nurses' confidence in assisting during RSI.

To conduct further research, Psychometric questionnaires can be used to gauge the competencies during RSI among Band 5 nurses before and after cue cards are given.
